OLD WINDSOR, BERKSHIRE:
SLAG LISTING

J G McDonnell BTech PhD MIFA

AML reports are interim reports which make available the results of specialist investigations in advance of full publication. They are not subject to external refereeing and their conclusions may sometimes have to be modified in the light of archaeological information that was not available at the time of the investigation. Readers are therefore asked to consult the author before citing the report in any publication and to consult the final excavation report when available.

Opinions expressed in AML reports are those of the author and are not necessarily those of the Historic Buildings and Monuments Commission for England.

Ancient Monuments Laboratory Report 3/93

OLD WINDSOR, BERKSHIRE:
SLAG LISTING

J G McDonnell BTech PhD MIFA

Summary

Ninety two kg of slag from the 1950s excavations were identified. The material included 62kg of smithing slag and 25kg of smelting slag, much of it apparently in redeposited contexts. Dating information is not yet available.

Old Windsor, Berkshire Slag Listing
Dr Gerry McDonnell

1 List Headings and Slag Descriptions

This listing contains the ironworking residues from the 1950's excavation at Old Windsor, Berkshire. The slag was identified and classified by Dr Gerry McDonnell. The list headings and other relevant information are given below:

OW	Year of Excavation
CONTEXT	Context number, those containing numbers => 99999 and described as 'de-stratified' under the 'Layer' heading were from boxes that had lost this information due to a flood.
TRENCH	A descriptor of the trench. The letters describe either the main feature found in the trench, eg GD=Great ditch.
LAYER	A description of the layer, including colour. For 'De-stratified' see Context. The information contains some shorthand descriptions which can be clarified by cross-referring to site stratigraphical information.
TYPE	The type of feature, some are obvious, eg pit, others are unclear.

The remaining headings are those used in other slag reports.

Ferrous Diagnostic Slags and Residues

SMITH	Smithing Slag - randomly shaped pieces of silicate slag generated by the smithing process.
HB	Hearth Bottom - a plano-convex accumulation of silicate slag formed in the smithing hearth.
TAP	Smelting Tap Slag - silicate slag generated by the smelting process, i.e. the extraction of the metal from the ore. Tap slag is the most characteristic form of this slag.
SMELT	Smelting Slag - randomly shaped pieces of smelting slag. It lacks the characteristic ropey texture of tap slag. It is usually characterised by flowed surfaces and large charcoal impressions.

Non-Diagnostic Slags and Residues

CIN	Cinder - high silica-content slag that can either be formed in a zone between smithing slag and the hearth lining or by high temperature reaction between silica and ferruginous material. It can be ascribed to either the non-diagnostic slags or the diagnostic slags depending on the iron content and its morphology.
FAS	Fuel Ash Slag - A very high silica slag (usually >90% silica) formed under high temperature oxidising conditions by the reaction of siliceous material and fuel ash. It is a non-diagnostic slag which can be formed in any hearth or fire at sufficiently high temperatures.
HL	Hearth Lining - the clay lining of an industrial hearth, furnace or kiln that has a vitrified or slag-attacked face.
ORE	Fragments of iron ore.
OTHER	Other Material - which comprises fragments of fuel, ferruginous stones etc..
OTYPE	Description of the Other material.
COMMENT	Free comment.

2 Summary Interpretation

A total of 92.5kg of slags and residues were recorded. It is not known whether the material represents 100% recovery or if a sampling procedure was used. In two cases the LAYER information noted that the slag retained was a sample.

The total weight of smithing slag (HB+SMITH) comprised 66% of the total recovered. The majority of this slag occurred in small deposits, a few hundred grammes, and only twelve contexts exceeded 1kg, excluding those that have been de-stratified. Similarly the combined weight of TAP and SMELT slag comprised 25% of the total, but was present in only 36 contexts, of which 7 contained more than 1kg (excluding the de-stratified contexts). Over 60% of the stratified HL (1.9kg) derived from a single context (1.19kg), the remainder occurred in small deposits.

This pattern of slag deposits would suggest that much of it was re-deposited, and not in its primary context. There was insufficient data to assess whether there was more than one phase or period of iron smelting and/or

iron smithing activity. There is sufficient smelting slag to confirm the presence of on-site smelting of iron. The presence of tap slag and smelting slag (including one furnace bottom) is not characteristic of any particular period. Tap slag is recovered from sites dating from the Iron Age to Medieval Periods. The iron smelting may be 'constructional', ie a one-off operation associated with the construction of building(s). A comparative example would be the slags recovered from excavation of a Roman Villa site at Amersham Mantles Green, Buckinghamshire (McDonnell 1986), which provided sufficient evidence to support the hypothesis of an initial period of smelting and smithing associated with the construction of the site, followed by continual smithing during the occupation of the site.

The Thames Valley does not contain 'commercial' ore deposits. Berkshire was noted in Tylecote's original work (1962) as one of the six English counties lacking known sources. However, bog ores were probably available for small scale exploitation.
